

Figure 1: The columns in base ten

Number systems and binary

In the first unit of this course, we look at binary numbers and binary representations of other sorts of data. See the video for a rationale, and a brief look at the founder of Information Theory, Claude Shannon.

The Man Who Turned Paper Into Pixels from Delve on Vimeo.

Positional numbering system

Our normal number system is a positional system, where the position (column) of a digit represents its value. Starting from the right, we have the ones column, tens column, hundreds, thousands, and so on. Thus the number 3724 stands for three THOUSAND, seven HUNDRED, two TENS (called twenty), and four ONES.

The values of those columns derive from the powers of ten, which is then called the **base** of the number system. The base ten number system is also called **decimal**.

There is nothing special about base ten, except that it's what you learned from a young age. A positional numbering system can use any quantity as its base. Let's take, for example, base five. In base five, the columns represent the quantities (from right to left) one, five, twenty-five, and a hundred twenty-five. We need to use five symbols to indicate quantities from zero up to four. For simplicity, let's keep the same numerals we know: 0, 1, 2, 3, and 4.

The number shown in this figure, 3104 in base five, represents the same quantity that we usually write as 404 in base ten. That's because it is three \times one hundred twenty-five (= 375), plus one \times twenty-five (= 25) plus four ones (= 4), so $375 + 25 + 4 = 404$.

You can count directly in base five; it looks like this: 0, 1, 2, 3, 4, 10, 11, 12, 13, 14, 20, 21, 22, 23, 24, 30, 31, 32, 33, 34, 40, 41, 42, 43, 44, 100. (Those correspond to quantities from zero to twenty-five.)

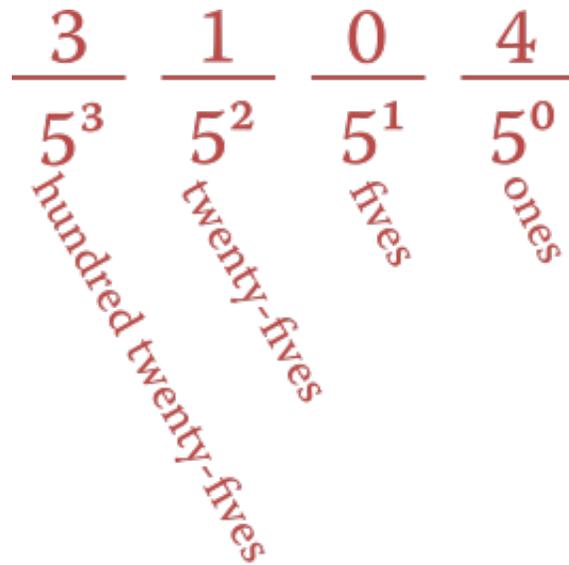

Figure 2: The columns in base five

There is a relatively simple **algorithm** for converting from base ten to any foreign base. Suppose we have the number 344 (three hundred forty-four) that we'd like to write in base five.

We start by dividing the number by the desired base, so $344 \div 5 = 68.8$. It helps to think of that as 68 with a **remainder** of 4. (The .8 corresponds to a remainder of 4 because $.8 \times 5 = 4$.) Remember the remainder, but proceed with the whole-number part. So now we divide $68 \div 5 = 13.6$ which is **remainder 3**. Next, $13 \div 5 = 2.6$, again **remainder 3**. Finally, $2 \div 5 = 0.4$, which is **remainder 2**.

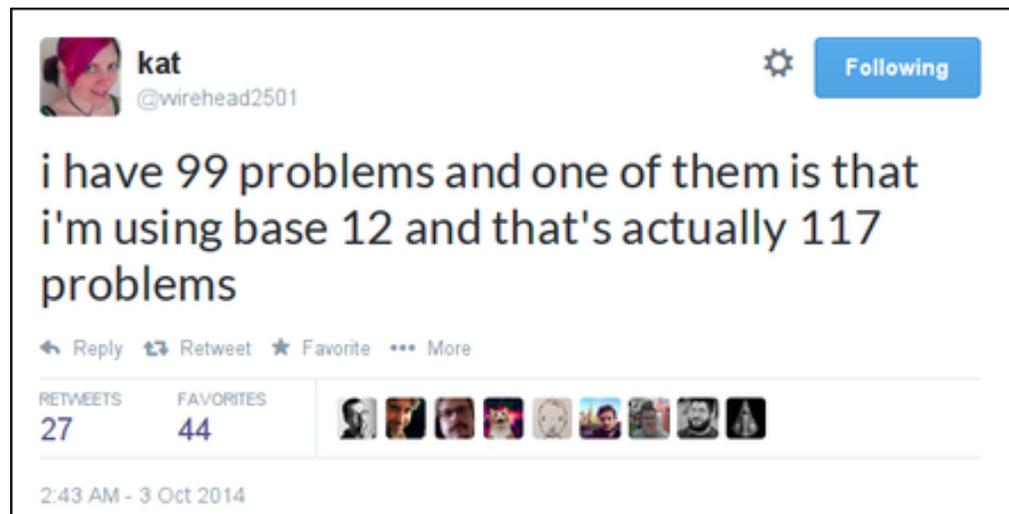

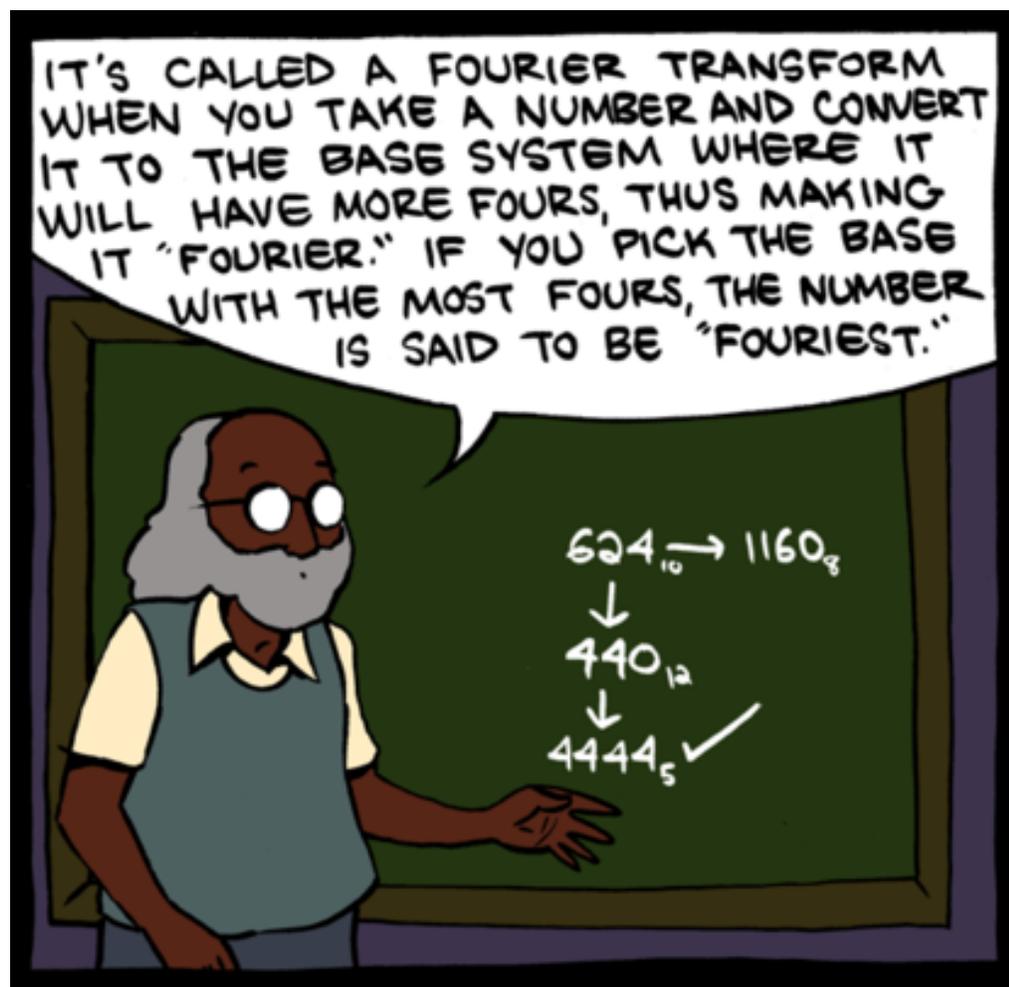

We stop when the whole-number part becomes zero, and then write the remainders from right to left: **2334**. Thus, 344 in base ten is written as '2334' in base 5.

Binary numbers

Computer systems use **binary** numbers – that just means they are in base **two**. Using two as the base is really convenient and flexible, because we need only two 'symbols' and there are so many ways we can represent them: zero/one, on/off, up/down, high/low, positive/negative, etc.

In binary, the columns are (from right to left) 1, 2, 4, 8, 16, 32, and so on. Using a zero means we exclude that column's quantity, and a one means we include it.

Figure 3: [wirehead2501](#) on TwitterFigure 4: Teaching math was way more fun after tenure – from [Saturday Morning Breakfast Cereal](#)

1	0	1	1	0
16	8	4	2	1
2^4	2^3	2^2	2^1	2^0

So the binary number 10110 is the quantity $16 + 4 + 2 = 22$. Each binary digit (a one or a zero) is called a **bit**. The largest five-bit binary number, then is $11111 = 16 + 8 + 4 + 2 + 1 = 31$.

It's worthwhile to learn to count in binary, at least from zero to fifteen:

0000 = 0	0100 = 4	1000 = 8	1100 = 12
0001 = 1	0101 = 5	1001 = 9	1101 = 13
0010 = 2	0110 = 6	1010 = 10	1110 = 14
0011 = 3	0111 = 7	1011 = 11	1111 = 15

The repeated division algorithm we learned in the positional numbering section also works for binary, but there's an even simpler way it can be adapted, by thinking in terms of even and odd numbers.

Let's convert the number 46 to binary. We begin by noticing that it is even, so we write a zero. Then we divide the number in half to get 23. That number is odd, so we write a one. Then we divide it in half (discarding the .5 remainder) to get 11. That's odd, so we write a one, and so on.

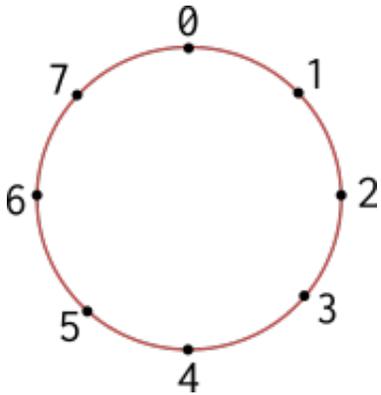

46	even	0
23	odd	1
11	odd	1
5	odd	1
2	even	0
1	odd	1

The algorithm ends when we get down to 1, and then we read the binary number from bottom to top: 101110 is the binary representation of the quantity 46.

Binary arithmetic

It's relatively easy to add numbers directly in binary. Line up the columns and then proceed from right to left, as usual. There are only four possible cases:

When you perform arithmetic with fixed-size numbers, you throw away any extra carry bit; the result cannot exceed the designated size. For example, see what happens if we try to add $110 + 011$ using 3-bit integers:

$$\begin{array}{r}
 \text{discard} \quad \textcircled{1} \\
 \text{extra carry} \quad 110 = 6 \\
 + 011 = 3 \\
 \hline
 001 = 1
 \end{array}$$

In 3-bit arithmetic, 6 plus 3 is 1. You can make sense of this on the number wheel. Addition corresponds to walking clock-wise around the wheel. So start at 6, and go clockwise by 3. That lands on 1, which is $6+3$.

Signed magnitude

Now we'll look at **signed** numbers – that is, numbers that can be positive or negative. There are two techniques for encoding signed numbers. The first one is called **signed magnitude**. It appears simple at first, but that simplicity hides some awkward properties.

Here's how it works. We use a fixed width, and then the left-most bit represents the sign. So 4-bit signed magnitude looks like this:

--- --- --- ---
 sign 4 2 1

where having the sign bit set to '1' means the magnitude is interpreted as negative. Thus, 0110 is +6 whereas 1110 is -6. In this system, the largest positive number is $0111 = +7$ and the most negative number is $1111 = -7$.

One of the unfortunate effects of this representation is there are two ways to write zero: 0000 and also 1000 . There is no such thing as negative zero, so this doesn't really make sense.

Two's complement

The second way to represent signed quantities is called **two's complement**. Although this looks trickier at first, it actually works really well. Below is the interpretation of 4-bit two's complement. All we need to do compared to normal unsigned numbers is negate the value of the left-most bit.

$$\begin{array}{cccc} \text{---} & \text{---} & \text{---} & \text{---} \\ -8 & 4 & 2 & 1 \end{array}$$

So +6 is 0110 as before, but what about -6? We need to turn on the negative 8, and then add two: 1010 . To represent -1, you turn on all the bits: 1111 , because that produces $-8+4+2+1 = -8+7 = -1$.

The nice thing about two's complement is that you can add these numbers and everything just works out. Let's try adding 7 and -3:

$$\begin{array}{r} 0\ 1\ 1\ 1 = 7 \\ 1\ 1\ 0\ 1 = -3 \\ \hline 0\ 1\ 0\ 0 = 4 \end{array}$$

It's also relatively easy to **negate** a number – that is, to go from +6 to -6 or from -3 to +3. Here are the steps:

1. First, flip all the bits. That is, all the zeroes become ones and all the ones become zeroes.
2. Next, add one.

For example here is how we produce -6 from +6:

$$\begin{array}{r} 0\ 1\ 1\ 0 = +6 \\ 1\ 0\ 0\ 1 \text{ (flip all the bits)} \\ + 1 \text{ (add one)} \\ \hline 1\ 0\ 1\ 0 = -6 \end{array}$$

You don't even have to reverse these steps in order to convert back:

4096	256	16	1
16^3	16^2	16^1	16^0

So a hexadecimal number like 2A5C has the value $2 \times 4096 + 10 \times 256 + 5 \times 16 + 12 \times 1 = 10844$ in base ten.

In hexadecimal, **each digit maps to exactly four bits**. So here is that same number in binary:

2	A	5	C
0 0 1 0	1 0 1 0	0 1 0 1	1 1 0 0
(8 4 2 1	8 4 2 1	8 4 2 1	8 4 2 1)

Below are two great video overviews of hexadecimal. (**Note** when you watch these – the Brits often pronounce zero as ‘naught.’)

Practice problems

3. Convert the following base ten (decimal) numbers into binary.
 - a. 6 _____
 - b. 18 _____
 - c. 51 _____
 - d. 63 _____

4. Convert the following unsigned binary numbers into base ten.
 - a. 1010 _____
 - b. 1101 _____
 - c. 1000 _____
 - d. 10001 _____

5. What do all **odd** numbers have in common, when written in binary? (Hint: try writing the quantities 3, 5, 7, 9, 11 in binary.)

6. Using 7-bit signed (two’s complement) binary numbers, what is the largest positive number? What is the most negative number?

7. Convert the following 5-bit **signed** (two's complement) binary numbers into base ten.

a. 01101 _____

b. 01111 _____

c. 10011 _____

d. 11111 _____

8. Convert the following 16-bit binary number into hexadecimal, and then into octal.

0 1 1 1 1 1 1 1 0 0 1 1 1 0 1 0

9. Convert the following hexadecimal numbers into binary:

a. 9D _____

b. C4 _____

c. A17E _____

10. Add and verify the following **unsigned** binary numbers.

$$\begin{array}{r} 1\ 0\ 1\ 1\ 1\ 1 \\ +\ 1\ 1\ 1\ 0\ 1 \\ \hline \end{array}$$

$$\begin{array}{r} 1\ 1\ 0\ 1\ 1\ 1 \\ +\ 1\ 0\ 0\ 1\ 0\ 0 \\ \hline \end{array}$$
