

The screenshot shows the GitLab Community Edition registration page. On the left, there is a header 'GitLab Community Edition' and a sub-header 'Open source software to collaborate on code'. Below this is a paragraph describing the platform's features: 'Manage Git repositories with fine-grained access controls that keep your code secure. Perform code reviews and enhance collaboration with merge requests. Each project can also have an issue tracker and a wiki.' On the right, there are two tabs: 'Sign in' and 'Register'. The 'Register' tab is active. The registration form includes fields for 'Name', 'Username', 'Email', 'Email confirmation', and 'Password'. The 'Password' field has a note: 'Minimum length is 8 characters'. A blue 'Register' button is at the bottom of the form. Below the button, there is a link: 'Didn't receive a confirmation email? Request a new one.'

Figure 1: GitLab registration form

Software setup

We will need the following software set up on whatever computer(s) you plan to use for this course. It should all work equally well on Mac, Windows, or Linux. These are somewhat ‘bare bones’ instructions, so ask questions [on the issue tracker](#) if you encounter any problems.

Git setup

- ⇒ [Video explanation](#) [14:33]

Git is a *version control* tool that helps developers keep track of any changes that are made to a set of files. We’ll also use it to submit and collaborate on assignments. You may have heard of GitHub, a social code-sharing site. We’ll be using a similar site, but on a private server.

1. Create an account at <https://gitlab.liu.edu/> (the “Register” tab). You’ll have to use your LIU email address to sign up. You should receive the confirmation link within a few minutes, otherwise check your junk folder too. After completing the registration, you can set a different email address in your profile, if you prefer.
2. Download the Git tool for your platform at <https://git-scm.com/downloads> and run the installer. The default settings should be fine.

3. Open the **Git Bash** application on Windows, or use **Utilities » Terminal** on Mac. Type these commands, **replacing your actual name and email address** in the double quotes:

```
git config --global user.name "YOUR NAME"  
git config --global user.email "YOUR.ADDRESS@EXAMPLE.COM"
```

4. If you know you already have an SSH key pair, you can skip this step. Otherwise, in the Git bash terminal enter `ssh-keygen`. You'll **press enter** for all the defaults, **including an empty passphrase**. It should go something like this:

```
$ ssh-keygen  
Generating public/private rsa key pair.  
Enter file in which to save the key (/c/Users/league/.ssh/id_rsa):  
Created directory '/c/Users/league/.ssh'.  
Enter passphrase (empty for no passphrase):  
Enter same passphrase again:  
Your identification has been saved in /c/Users/league/.ssh/id_rsa.  
Your public key has been saved in /c/Users/league/.ssh/id_rsa.pub.  
The key fingerprint is:  
b7:27:3e:8d:83:df:9a:21:c7:27:0d:fa:43:ac:d0:7e league@WIN7
```

5. Now you'll want to access the *public* part of the key that it generated. It's easiest to open it in a text editor, using:

- On Windows: `notepad .ssh/id_rsa.pub`
- On Mac: `open -e .ssh/id_rsa.pub`
- On Linux: `cat .ssh/id_rsa.pub`

The editor will pop up with a line that begins `ssh-rsa AAAA...` copy the whole thing onto your clipboard.

6. Log in to your gitlab.liu.edu account. From your user icon in the upper right, select **Settings**, then **SSH Keys**. Paste your public key into the big text box, then use the green button **Add SSH Key**. The title should populate automatically when you click it. If not, just enter "my key" or a nickname to identify your computer, like "my Dell laptop."
7. Use the upper left menu to go back to your projects list. Click the green **New Project** button. In the **project path** box, leave the drop-down set to your username, but enter your last name followed by `-CS164` (no spaces) for the **project name**. Keep the visibility level private, then confirm with the green **Create Project** button.
8. Your new project page will say "The repository for this project is empty." Click the **adding a README** link below that. You'll be placed in a text editor with the title `README.md`. Type your name and something about yourself:

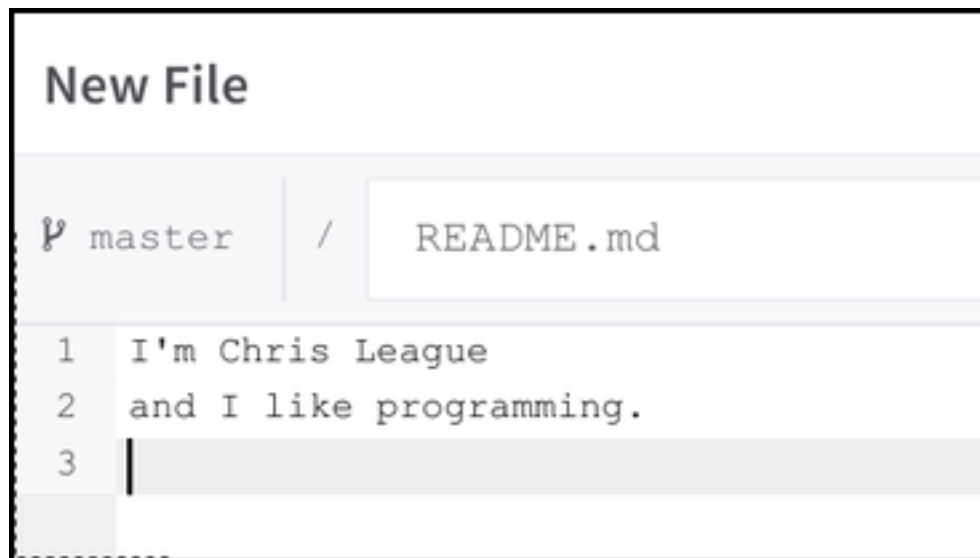

Figure 2: Add new README file

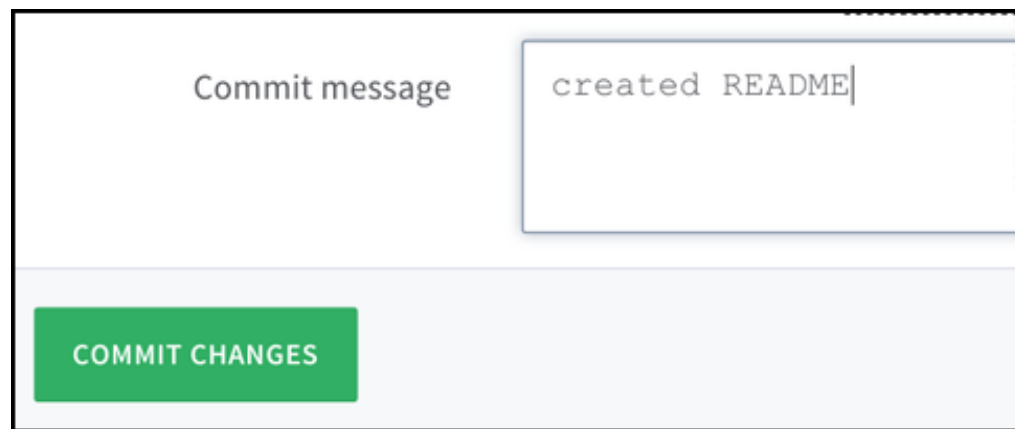

Figure 3: Specify message and commit changes

9. Below the editor is space for a **Commit message**. In that box, type something like “Created README,” (it may already be filled for you) and then click the green **Commit Changes** button.
10. Next, while looking at your project page, click the **gear icon** near the upper right, then select **Members**. In the **Search for members** box, type league and select the user just named league, with my picture. Change the **permissions drop-down** to **Developer** and then click the green **Add to Project** button.

Clone and sync

Now we'll use the installed Git system to connect a folder on your machine to your new project on the GitLab server.

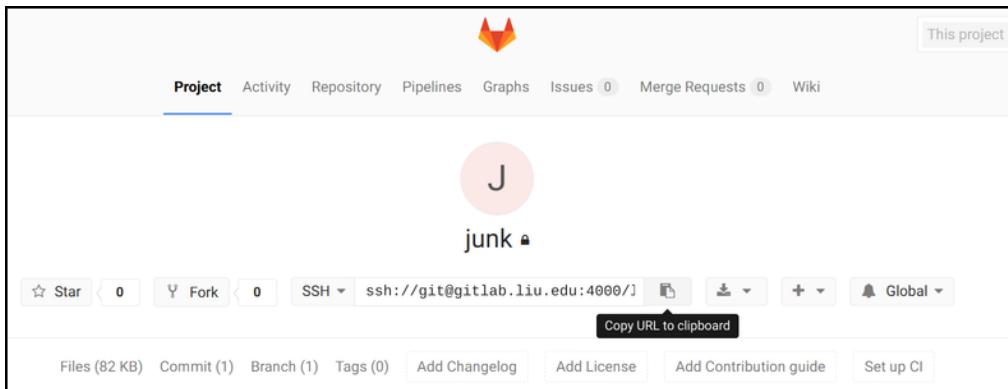

Figure 4:

- Decide where you want the folder to live, such as in your Desktop or Documents folder. Open up **Git Bash** (Windows) or **Utilities » Terminal** (Mac) and go to your selected directory using the `cd` command:

```
cd Desktop
```

- On your GitLab project page, find the `ssh://git` address and copy that entire thing to your clipboard. (The button just to its right will probably work.)
- Back in your bash/terminal, type `git clone` and then paste in the URL. (On Windows, control-V may not work to paste, but there should be a paste option on the right-click menu.)

After the address, add another space and then the name of the new folder that will be synchronized. I'd recommend just naming it after the course (CS164 or maybe CS164-repo).

Here's the complete command (your address will differ):

```
git clone ssh://git@gitlab.liu.edu:4000/USER/NAME-CS164.git CS164
```

Hit enter. Here's a transcript of what will happen:

```
Cloning into 'CS164'...
remote: Counting objects: 3, done.
remote: Total 3 (delta 0), reused 0 (delta 0)
Receiving objects: 100% (3/3), done.
```

Now you have a new folder containing your `README.md`.

- Descend into that new folder in your terminal, using `cd`:

```
cd CS164
```

15. Use an editor on your system to make some kind of change to the `README.md`. If I've recommended an IDE to you, you can do it there. Or you can install one of these:
- On Windows: [Notepad++](#)
 - On Mac: [Sublime Text](#)
 - On Linux: `gedit`

Just add another sentence or so to the file.

16. Git will be able to detect the change you made, and then you can snapshot it (called a **commit**) and synchronize it with the project on the GitLab server (called **pull** and **push**). The sections below describe how, either using purely the command-line, or using a GUI. Choose one, or try both.

Using just command line

- ⇒ [Video explanation](#) [12:56]

17. First I try to orient myself using the command `git status`. It outputs:

```
On branch master
Your branch is up-to-date with 'origin/master'.
Changes not staged for commit:
  (use "git add <file>..." to update what will be committed)
  (use "git checkout -- <file>..." to discard changes in working directory)
```

```
    modified:   README.md
```

```
no changes added to commit (use "git add" and/or "git commit -a")
```

Which means it recognized my modification to the file. To see exactly what changed within the file, you can optionally do `git diff`. It outputs:

```
diff --git a/README.md b/README.md
index e69de29..18249f3 100644
--- a/README.md
+++ b/README.md
@@ -0,0 +1 @@
+Hello world.
```

The plus signs indicate lines added (usually green), minus signs indicate lines deleted (usually red).

18. Now we specify what changes to include in this commit (snapshot):

```
git add README.md
```

You can specify multiple files at once, just separate them with spaces. If there are **new** files you created and want to commit, you would specify them there too.

Once you add the file, they are “staged” for commit, and another `git status` (optional) will report that.

19. Now we tell it to create the commit. Each commit automatically includes a timestamp and your name and email address. (You provided them earlier, using `git config`.) But you also have to specify a “commit message” – a short piece of text that describes what you changed, or what you’re committing. The complete command is like this:

```
git commit -m "Added another sentence to README"
```

The output is something like:

```
[master 5b611c8] Added another sentence to README
 1 file changed, 1 insertion(+)
```

That hexadecimal number beside `master` (in my case, `5b611c8`, but yours will be different) identifies the commit. Optionally, you can see a history of the commits using `git log`.

20. A snapshot of your files has been saved locally, but it’s not yet available on the GitLab server. To synchronize with the server, I recommend this compound command:

```
git pull && git push
```

The pull portion brings down any changes on the server that you don’t have locally. And then – only if that succeeds – it will push your local changes up to the server.

The pull could fail if there is a **conflict** – changes on the server that interfere with changes that you’ve made locally, in the same files. If that happens, you will have to fix the conflicts locally, add the changes, commit again, and then try to synchronize again.

21. Assuming the push succeeds, you should be able to visit the project page on GitLab and see the updated README file.

Using the built-in GUI

22. To start using the built-in GUI on your local repository, make sure you are in the correct directory, and then run:

```
git gui
```

Figure 5: The built-in GUI

The GUI window shows the current status. In the screenshot above, we have one file modified, and it already shows the differences. Plus signs indicate lines added (in green), and minus signs indicate lines deleted (in red).

23. To specify what changes to include in this commit (snapshot), we need to move them to the “Staged Changes” section (lower left). You select one or more files in the Unstaged Changes and double-click them or use **Commit** » **Stage to Commit** from the menu, or press Ctrl-T.

If there are **new** files you created and want to commit, you would stage them too.

24. Each commit automatically includes a timestamp and your name and email address. (You provided them earlier, using `git config`.) But you also have to specify a “commit message” – a short piece of text that describes what you changed, or what you’re committing. Type your commit message into the box in the lower right.

Then you can hit the **Commit** button. The status bar at the bottom of the window will say “Created commit 5b611c8” or similar. That hexadecimal number (yours will be different) identifies the commit.

Optionally, you can see a history of the commits by selecting **Repository** » **Visualize All Branch History** from the menu.

25. A snapshot of your files has been saved locally, but it’s not yet available on the GitLab server. To synchronize with the server, I’d first recommend fetching and merging any changes:

- Use **Remote » Fetch from » origin**, and then *if* it reports any changes,
- Use **Merge » Local Merge**.

The fetch brings down any changes on the server that you don't have locally. The merge portion could fail if there is a **conflict** – changes on the server that interfere with changes you've made locally, in the same files. If that happens, you will have to fix the conflicts locally, add the changes, commit again, and then try to synchronize again.

Next, you can hit the **Push** button next to the commit message box, and confirm it in the following dialog.

26. Assuming the push succeeds, you should be able to visit the project page on GitLab and see the updated README file.
